Diabetic nephropathy remains a leading cause of end-stage renal disease (ESRD) in western societies, accounting for about 40% of all patients beginning renal replacement therapy. Patients with type 2 diabetes comprise the largest and fastest growing single disease group requiring renal replacement therapy. In addition to the high risk of progression to ESRD, diabetic nephropathy is associated with a very high risk of cardiovascular (CV) morbidity and mortality, which is not abolished by dialysis or renal transplantation. Over the past two decades there have been major advances in our attempts to understand the risk factors for development and progression of diabetic renal dysfunction, that have resulted in better characterisation of the natural history of this serious complication. Effective antihypertensive treatment and aggressive management of CV risk factors have helped improve the prognosis of patients with overt diabetic nephropathy, particularly those with type 1 diabetes. However, for the larger proportion of patients with type 2 diabetes, the renal and CV prognoses are still poor. Recently, more focus has been placed on treating diabetic patients early in order to prevent future organ damage. Microalbuminuria is an

important intermediary end-point that correlates strongly with CV mortality in all people with diabetes as well as progression to ESRD in people with type 1 diabetes. We can now identify patients at high risk early in the natural history of their disease. Clinical trials have uniformly shown that in the early disease history of diabetes, achievement of both tight glucose control, eg, HbA1c <7%, and tight blood pressure control eg, blood pressure <140/90 mm Hg, substantially reduces CV events and progression of nephropathy. In latter stages of diabetes, tight blood pressure control has a relatively greater impact on CV risk reduction as compared to tight glucose control. The challenge for the practising physician, however, is to maximally utilise the available modalities of treatment to prevent progression to overt nephropathy and reduce the associated high risk of CV morbidity and mortality. In the early 21st century, the patient with type 2 diabetes will need to be the specific focus for use of these preventive treatment modalities due to the geometric risk in the international incidence of this disease.

Introduction

Diabetic nephropathy (DN) remains a leading cause of end-stage renal disease (ESRD) in western societies. Diabetes is the single largest cause of ESRD in American and European adults, accounting for over one-third of all patients enrolling onto renal support therapy programmes.^{1–3} Approximately 50–60% of patients with diabetic nephropathy have type 2 diabetes. Indeed because of the increasing prevalence of type 2 diabetes and the longer survival of patients, they now comprise the largest and fastest growing single disease group requiring renal replacement therapy in the general population.

Diabetic nephropathy is conventionally defined as

the clinical syndrome characterised by persistent albuminuria (>300 mg/24 h or >200 µg/min), detected on two or more occasions over a period of several months. Patients invariably demonstrate associated hypertension, a predictable and relentless decline in glomerular filtration rate (GFR) and a progressive increase in proteinuria.⁴ In this review article, we shall concentrate on the importance of early detection of nephropathy and the role of available treatment modalities to improve renal and cardiovascular outcomes.

Epidemiology

The cumulative incidence of nephropathy appears to be similar in both type 1 and type 2 diabetes.^{4,5} Traditionally, nephropathy occurs in 30–40% of patients with type 1 diabetes. The majority of these patients will, without specific intervention, develop ESRD within 10–15 years from the onset of overt DN.
